Outline

Introduction

Inflationary density fluctuations and flow fluctutaions

Power spectra

- 4 Effect of magnetic field on flow
- 5 Summary and Conclusions

A .

- Inhomogeneities of all scales are present in the initial state energy density distribution in heavy-ion collisions.
- We argued that these inhomogeneities will generate flow fluctuations, both even and odd, for harmonics upto, say n = 30.
- It is important to calculate the root-mean-square values of these flow fluctuations than the averages.
- A plot of the rms values of the Fourier transforms of the flow fluctuations v_n^{rms} vs. *n* will contain important information about the initial state fluctuations and their evolution.

- These density fluctuations are similar to the density fluctuations in the early universe which leave their imprints in the cosmic microwave background radiation as temperature fluctuations.
- Inflationary density fluctuations are present on all scales and after inflation, the scales larger than the horizon scale 'enter' the horizon, the shortest scale first and evolve.
- In heavy-ion collisions, thermalisation happens in less than a fm/c. The system has fluctuations of orders larger than this thermalisation scale, all the way upto the system size.

< 回 > < 三 > < 三 >

- These energy density fluctuations grow into momentum anisotropies, the shortest modes first. The higher harmonics grow first. Elliptic flow being the largest mode will grow to it maximum last.
- The relevant scale one should compare with the modes is the acoustic horizon at a given time.
- The larger modes like elliptic flow may not completely grow to the corresponding momentum anisotropy before freeze-out.

< 回 > < 三 > < 三 >

- We have argued that the growth of a spatial fluctuation to the corresponding momentum fluctuation will depend on the size of the mode compared to the acoustic horizon scale.
- Thus the elliptic mode of spatial eccentricity in smaller systems should grow faster compared to that in larger systems if the thermalisation time scales are similar.

Growth of ϵ_p/ϵ_x for systems of different size. Smooth Glauber initial conditions are used.

- Another important aspect of inflationary density fluctuations is the acoustic oscillations. The over/under densities which enter the horizons grow and oscillate acoustically.
- We have argued that the sub-horizon modes density fluctuations in heavy-ion collisions also should display an oscillatory behavior.
- Following CMBR fluctuation analysis, a natural observable to look at would be the Fourier co-efficients of the azimuthal anisotropies in the final particle momenta in a given rapidity bin. (CMBR anisotropic fluctuations are studied by expanding them in spherical harmonics.)
- We study the Fourier co-efficients of the azimuthal anisotropy of momenta given by ^{ρ(φ)-p_{av}}/_{p_{av}}.

Effect of magnetic field on flow

- Presence of magnetic field in the early universe distorts the power spectrum of CMBR. This is due to the complex dependence of magnetosonic waves on magnetic fields and density gradients.
- We studied the effect of magnetic field on flow in heavy-ion collisions.
- In non-central collisions, a large magnetic field is generated during the collisions. The time scale of this field can be several fm due to induced currents in the plasma.
- We argued that this can enhance flow anisotropies. It is interesting to see whether larger values of viscosity can be accommodated in this scenario.

< 日 > < 同 > < 回 > < 回 > < □ > <

- In presence of magnetic field, there are three types of waves in the plasma in place of ordinary sound waves.
- We calculated the flow anisotropies by using the generalised sound waves, the fast magnetosonic waves which have significant contributions from the magnetic pressure.
- The expression of group velocity of the fast magnetosonic waves is given by

$$v_{gr} = v_{ph} \left[\mathbf{n} + \mathbf{t} \frac{\sigma \pm 2\delta(\mathbf{a} \mp (1 + \cos^2 \theta) \sin \theta \cos \theta)}{2(1 + \delta \cos^2 \theta \pm \mathbf{a})\mathbf{a}} \right]$$

•
$$\delta = \frac{c_s^2 v_A^2}{\left(\frac{4\rho}{3\omega}c_s^2 + v_A^2\right)}, \sigma = \frac{4c_s^2 v_A^2}{\left[\left(\frac{4\rho}{3\omega}\right)c_s^2 + v_A^2\right]^2}, \omega = \left(\frac{4\sigma}{3}\right) + B^2$$

Summary and Conclusions

- The first peak contains information about the freezeout stage, and the dominant scale of fluctuations.
- We plot v_n up to n = 30, which corresponds to wavelength of fluctuation of order 1 fm. There will be some scale (probably less than 1 fm) below which hydrodynamics breaks down. A changeover in the plot of v_n at some large n will indicate applicable regime of hydrodynamics.
- One important factor which can affect the shape and inter-spacings of these peaks, is the nature and presence of the quark-hadron transition.
- Magnetic field leads to complex flow patterns, vorticity generation. There are some interesting results already from MHD. The odd harmonics seem to be suppressed in presence of magnetic field.
